# Project scope

This project is a code generator for database driven projects.

It reads relational databases, and based on program metacode it creates programming code for projects.

The project can adapt to any relational database and most program languages and frameworks.

Extra programming needs to be done if additional database tools need to be accessed.

Extra programming languages and frameworks are defined in the template definitions and are maintained in a metacode map and required no changes in the Metacoder programming.

This makes it a very powerful tool that can adapt to a lot of programming environments and databases.

The content comes from the database structure and the delivered metacode, giving a programmer full control over the end result.
